

Basic Input and Output functions and codes in C# console

So today I am going to explain about all the input and output functions present in C# console by the help of which you can print text and take input from users. So lets move now.

Output/Print codes

There are two codes used to print any text in terminal, these are `Console.WriteLine` and `Console.Write`, both of them are used to print but both have a small difference.

- **Console.WriteLine** — If you type two lines of text then the two lines will be printed in two different lines.
- **Console.Write** — If you type two lines of text then the two lines of text will be printed in the terminal in same lines.

Now lets code our first program coding a simple program.

Example 1 — Using Console.WriteLine:

```
using System;
class Program
{
    static void Main(string[] args)
    {
        Console.WriteLine("Hello its my 1st C# code");
    }
}
```

Example 2 — Using Console.Write:

```
using System;
class Program
{
    static void Main(string[] args)
    {
        Console.Write("Hello its my 1st C# code");
    }
}
```

Open your terminal and code it first. If your output comes the text written in the close brackets (parenthesis) then congratulations 🎉 you have coded your first program!

Now the hometask will be to print different text using the two given code blocks. Note: write the code from beginning, don't copy and paste it, otherwise you will not be a good coder.

Note: C# is case sensitive. If you type something unusual like `Console.writeLine` instead of `Console.WriteLine`, or if you type in small letter a code which has to be in caps, then an error will show in terminal. Remember to give semicolon (;) after each code ends.

Input/User_defined codes

The main purpose of this code is to take input from the user and display it in terminal.

`Console.ReadLine()` and `Console.Read()` again both have the same functions to take user input but both have a difference:

- **Console.ReadLine()** — used to take input string or a set of characters.
- **Console.Read()** — used to take a single character or a letter.

Now lets code our first program coding a simple program.

Example 3 — Using Console.ReadLine() to take full name input:

```
using System;
class Program
{
    static void Main(string[] args)
    {
        Console.WriteLine("Hello enter your name : ");
        string name = Console.ReadLine();
        Console.WriteLine("Your name is " + name);
    }
}
```

Example 4 — Using Console.Read() to take a single character input:

```
using System;
class Program
{
    static void Main(string[] args)
    {
        Console.WriteLine("Hello enter your name : ");
        char name = (char)Console.Read();
        Console.WriteLine("Your name is " + name);
    }
}
```

After you write your code and run it, the terminal will ask you for entering your name. Write your name and when you press the enter button it will print: `Hello : your name`.

Congratulations 🎉 you have made your first code for user input! At the very next day I will make you learn what variables are and different data types. Practice your code, goodbye 😊
